Biodegradability

Conditions : Biodegradation is fastest under specific conditions: controlled industrial settings with warmth (50-60°C), moisture, and microbes, but natural materials break down in soil/compost too.

Definition : Biodegradability is a material's ability to be broken down naturally by microorganisms (like bacteria, fungi) into simpler, harmless substances (water, CO2, biomass), returning to nature without pollution, with the rate depending on material structure and environmental condition.

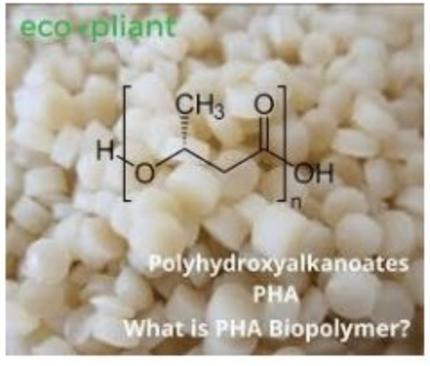

Highly biodegradable materials

Non Biodegradable materials
